Attachments: C5HF9O3.tif; C4HF7O3.tif

Yes, I planned to draw the protonated structures, but couldn't have the drawing software installed in my office computer yesterday...Now have them drawn in my personal computers. I will send out the email to the editor later today.

For this draft I coped the structure in Mark's paper, but before I send it to the editor I will redraw them with the same software I used for other compounds to make the appearance more uniformed.

I am the corresponding author of the paper "Legacy and Emerging Perfluoroalkyl Substances Are Important Drinking Water Contaminants in the Cape Fear River Watershed of North Carolina" published in Env. Sci. & Tech. Letters 2016 3 (12) 415 (DOI: 10.1021/acs.estlett.6b00398). The authors were recently contacted about two of the molecular structures we are showing in the supporting information of the paper. The suggestion was made that the two chemicals are more likely branched instead of linear as follows:

Chemical	Structure shown in current IS	Should be changed to
PFMOPrA		PFMOBA		
After a review of our high resolution mass spectrometry results, we concur that the branched structures are more likely.

I would like to know whether it is possible to update the SI of the above referenced paper. The revised SI with the two chemical structures updated is in the attachment. Since we do not need to change anything in the paper itself but only the SI, could we just replace the SI document without a formal erratum? Thank you very much and I apologize for the inconvenience.

If it is easy to change the SI lets do it. If it is not, it is really not a big deal. Plus we have not standard to confirm which is correct. Could be both. Paul Resnick seems to think the branched isomers are more likely.

Sorry for the mistake... if updating the SI is not too much trouble, I'd say let's try it.

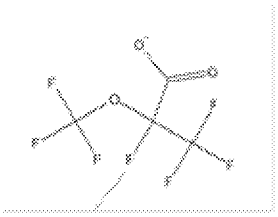
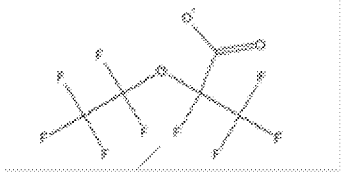
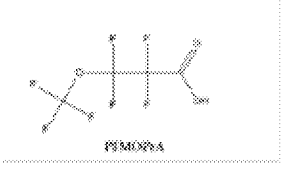
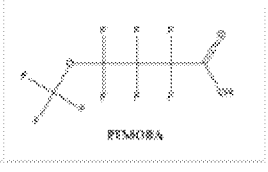
In our paper Strynar et al., 2015 we proposed these structures as below: (Figure S7). These are the ones Paul suggests are more likely.





In Sun et al., 2016 we showed them different (Figure S1).





I should have noted this in the SI.

The QTOF can distinguish between the two as the likely breaking point is at the ether oxygen. We would get different fragments for the PFMOBA, not the PFMOPrA.

Interesting... But Synquest does make the non-branched compounds we are showing (see first two compounds in the attached). Would QTOF work be able to distinguish between linear and branched?

I believe that the structural assignments for PFMOBA [$CF_3OCF_2CF_2CF_2COOH$] and PFMOPrA [$CF_3OCF_2CF_2COOH$] are most likely incorrect.

More reasonably the correct structures are isomers $CF_3CF_2OCF(CF_3)COOH$ and $CF_3OCF(CF_3)COOH$ respectively. I doubt that the MS/MS could tell the isomers apart.

If you want to discuss this further please call me. (703) 567-6832.

Best regards,

Paul
